```
try

except

else
```

```python
try:
    ...
except ...:
    ...
else:
    do_something()
```

Code that executes if the try clause does not raise an exception

Why? Avoid accidentally catching an exception
raised by something other than the code being protected

Example: Database Transactions

```python
try:

    update_the_database()

except TransactionError:

    rollback()

    raise

else:

    commit()
```

If the commit raises a TransactionException,
we might actually *want* to crash
